ABSTRACT

A collocation formulation is used as the basis for a unified approach to the various quasi-static aero-thermo-elastic problems. These problems include rigid and flexible load distributions, divergence, estimation of rigid and flexible static and dynamic stability derivatives, and the correction of wind tunnel data measured on flexible models. The formulation utilizes structural, thermal, and aerodynamic influence coefficients.

The Aerospace IBM 7090 Computer Program No. LD003A provides the solution to the above problems. The program capacity is fifty collocation control points and ten values of dynamic pressure.

SYMBOLS

a	Element of flexibility matrix
a_T	Element of thermal influence coefficient matrix
b_r	Reference semichord
C_h	Element of oscillatory aerodynamic influence coefficient matrix
C_{hs}	Element of steady aerodynamic influence coefficient matrix
C_l	Aerodynamic rolling moment coefficient
C_m	Aerodynamic pitching moment coefficient
C_z	Aerodynamic normal force coefficient
C_z	Element of aerodynamic normal force coefficient distribution matrix
$C_z^{(e)}$	Element of experimentally determined aerodynamic normal force coefficient distribution matrix
c	Local chord
\bar{c}	Mean aerodynamic chord
\tilde{c}	Average chord
c_l	Local spanwise lift coefficient
F	Element of force matrix
H	Generalized reference deflection
H_o	Reference deflection for initial deflection mode
h	Element of deflection matrix
I	Element of unit matrix
K	Flexibility matrix normalizing constant
k_r	Reference reduced frequency

ζ	Rolling moment
M	Element of mass matrix; bending moment
m	Pitching moment
N	Reference load factor
n	Element of load factor matrix
q	Dynamic pressure
q_{div}	Divergence dynamic pressure
S	Surface reference area
s	Surface span measured from root to tip
T	Reference temperature; torque
t	Element of temperature distribution matrix
V	Shear
W	Element of aerodynamic weighting matrix
x, y	Cartesian coordinates
\bar{x}, \bar{y}	Coordinates of aerodynamic center
x_o	Coordinate of pitching moment reference axis
Z	Normal force
$\Delta()$	Denotes incremental value
θ	Angle of pitch
λ	Eigenvalue
ξ	Control point location as fraction of local chord
ρ	Atmospheric density
ω	Frequency

(

Subscripts

a	Aerodynamic
f	Flexible
H, T, N	As subscript to C_Z , C_m , and C_l , denotes partial differentiation with respect to H, T, or N, respectively, e.g., $C_{ZH} = \partial C_Z / \partial H$; as subscript to C_Z , merely denotes reference to H, T, or N
i	Inertial; also used as dummy index, e.g., Δy_i denotes width of <u>i</u> th strip
m	Model; moment
o	Initial value
r	Rigid

Matrices

[]	Square
{ }	Column
[]	Row
[] ⁻¹	Inverse
[]	Diagonal

}

SECTION I

FORMULATION OF PROBLEM

A. Introduction

The most general numerical formulation that can be made of the various aeroelastic problems is a collocation formulation expressed in terms of matrices of structural, inertial, and aerodynamic influence coefficients. Such a formulation of the flutter problem has been discussed in Ref. 1, and of the static aeroelastic problems in Ref. 2. The present report reconsiders the static aeroelastic problems by reviewing the derivations and extending the computational procedures of Ref. 2 in treating the problems of rigid and flexible load distributions, divergence, estimation of rigid and flexible static and dynamic stability derivatives, and correction of wind tunnel data measured on flexible models.

The basis for the present generalized aero-thermo-elastic analysis is found in recent advances in both aerodynamic and structural theories. The aerodynamic developments have proffered aerodynamic influence coefficients based on a number of theories, covering the entire Mach number range of current interest. The structural developments have provided structural and thermal influence coefficients for external and temperature loadings, respectively, for surfaces of arbitrary aspect ratio. The current state of the art of aerodynamic and structural influence coefficient analyses is surveyed in Refs. 3 and 4, respectively.

B. Sign Convention

We choose the NASA body stability axis system as our coordinate system: x forward, y starboard, and z down. Positive loads and deflections are in the same directions, and positive moments are given by applying the right-hand rule to the coordinate directions.

C. Derivation of Equations

The force distribution $\{F\}$ acting on a flexible lifting surface or body arises from two sources: the aerodynamic forces resulting from the attitude (as specified by the deflection mode $\{h\}$), and the inertial forces resulting from a distribution of load factor $\{n\}$. The aerodynamic forces are found from the weighted (the weighting matrix must be derived from experimental data on the force changes resulting from changes in attitude; see Refs. 5 and 6) steady aerodynamic influence coefficients (AICs), and/or a set of experimentally determined control point force coefficients

$$\{F_a\} = (qS/\bar{c})[W][C_{hs}] \{h\} + qS \{C_{zr}^{(e)}\} \quad (1)$$

The use of the experimental force coefficients is generally necessary to account for the aeroelastic behavior arising from camber and/or wing-body interference. The inertial forces are found from the mass matrix

$$\{F_i\} = [M] \{n\} \quad (2)$$

The total force distribution therefore becomes

$$\{F\} = \{F_a\} + \{F_i\} \quad (3a)$$

$$= (qS/\bar{c})[W][C_{hs}] \{h\} + qS \{C_{zr}^{(e)}\} + [M] \{n\} \quad (3b)$$

The deflection mode $\{h\}$ is composed of the initial deflection mode of the rigid surface $\{h_r\}$ * the thermal distortion mode (which may be considered to be initially built in) which is found from the incremental temperature distribution and the matrix of thermal influence coefficients (TICs), and the deformation mode of the flexible surface $\{h_f\}$

$$\{h\} = \{h_r\} + [a_T]\{t\} + \{h_f\} \quad . \quad (4)$$

The deformation mode of the flexible surface is found from the total force distribution and the matrix of structural influence coefficients (SICs)

$$\{h_f\} = K[a] \{F\} \quad , \quad (5)$$

where K is a normalizing factor to the SICs (introduced for convenience in studying variations in stiffness levels). Combining Eqs. (3b), (4), and (5) permits the solution for the deformation mode

$$\{h_f\} = K[A][a] \{F_r\} \quad , \quad (6)$$

where $\{F_r\}$ is the force distribution on the rigid system (again considering the thermal distortion to be initially built in).

$$\{F_r\} = (qS/\bar{c})[W][C_{hs}] (\{h_r\} + [a_T]\{t\}) + qS\{C_{zr}^{(e)}\} + [M]\{n\} \quad , \quad (7)$$

* A distinction is made later in the derivation [see discussion preceding Eq. (31)] between two sources of the initial deflection mode: that arising from any built-in twist or camber and that arising from the attitude (sometimes called the additional deflection mode). The program computes the initial deflection mode as the sum of these, $\{h_r\} = H_0\{h_r/H_0\} + H\{h/H\}$, and both sets of data are required. The distinction is not made at this point because it is not essential to the derivation.

where

$$[A] = ([I] - (KqS/\bar{c})[a][W][C_{hs}])^{-1} \quad (8)$$

The total force distribution is found by returning to Eq. (3b) with Eqs. (4) and (6)

$$\{F\} = [B]\{F_r\} \quad (9)$$

where

$$[B] = [I] + (KqS/\bar{c})[W][C_{hs}][A][a] \quad (10)$$

For the purpose of structural analysis, it is often convenient to convert the control point forces into the structural loads of shear, moment and torque at particular stations. A set of transformation matrices may be defined to compute

the shear

$$\{V\} = [V/F]\{F\} \quad (11)$$

the moment

$$\{M\} = [M/F]\{F\} \quad (12)$$

and the torque

$$\{T\} = [T/F]\{F\} \quad (13)$$

Each element in the load coefficient matrices is the load at a particular station due to a unit control point force.

In certain longitudinal problems, it is desirable to adjust the attitude so that the flexible system sustains a specified total aerodynamic force. If we denote the specified total by Z , then

$$[I] \left(\{F\} - [M]\{n\} \right) = Z \quad (14)$$

and if we extend the definition of $\{h_r\}$ in Eq. (4) to include the change in pitch attitude, we have

$$\{h_r\} = \{h_{r_0}\} - \Delta\theta\{x\} \quad (15)$$

The substitution of Eqs. (7), (9), and (15) into Eq. (14) leads to the solution for the incremental pitch angle

$$\Delta\theta = (1/D)(C - Z) \quad (16)$$

where

$$C = [I] \left([B]\{F_{r_0}\} - [M]\{n\} \right) \quad (17)$$

$$D = (qS/\bar{c})[I][B][W][C_{hs}]\{x\} \quad (18)$$

and

$$\{F_{r_0}\} = (qS/\bar{c})[W][C_{hs}] \left(\{h_{r_0}\} + [a_T]\{t\} \right) + qS\{C_{zr}^{(e)}\} + [M]\{n\} \quad (19)$$

The final force distribution in this case follows from Eqs. (7), (9), (15), and (19)

$$\{F\} = [B]\{Fr_o\} - \Delta\theta(qS/\bar{c})[B][W][Ch_s]\{x\} \quad (20)$$

The final deflection mode follows from Eqs. (4), (5), (15), and (20)

$$\{h\} = \{hr_o\} - \Delta\theta\{x\} + K[a]\{F\} + [a_T]\{t\} \quad (21)$$

A variation of the foregoing is found in maintaining a constant total force equal to that given by the rigid condition (without the thermal distortion). In this case

$$Z = qS[I] \left((1/\bar{c})[W][Ch_s]\{hr_o\} + \{C_{zr}^{(e)}\} \right) , \quad (22)$$

and Eqs. (16), (17), (18), (20), and (21) provide the solution for the final force distribution and deflection mode.

The possibility of divergence is seen in Eq. (6) as the inverse of the matrix [A] approaches singularity. The critical values of (Kqs/\bar{c}) that yield a singularity are related to the eigenvalues of the matrix, and the divergence condition is specified by the eigenvalues of the equation

$$\lambda\{h_f\} = [a][W][Ch_s]\{h_f\} , \quad (23)$$

where

$$\lambda = \bar{c}/KSq_{div} , \quad (24)$$

from which the divergence dynamic pressure is found

$$q_{div} = \bar{c}/\lambda KS \quad (25)$$

Any positive value of q_{div} shows a divergence possibility although usually only the first or second values have any practical significance. The corresponding eigenvectors of Eq. (23) are the divergence modes.

The foregoing development of the force distribution on the flexible system provides the basis for estimating aerodynamic stability derivatives. The aerodynamic coefficients are defined by the following:

$$C_Z = Z/qS \quad (26a)$$

$$= (1/qS)[I] (\{F\} - [M]\{n\}) \quad (26b)$$

$$C_m = M/qS\bar{c} \quad (27a)$$

$$= -(1/qS\bar{c})[x - x_o] (\{F\} - [M]\{n\}) \quad (27b)$$

$$C_l = L/qSs \quad (28a)$$

$$= (1/qSs)[y] (\{F\} - [M]\{n\}) \quad (28b)$$

The center of pressure is found from

$$(\bar{x} - x_o)/\bar{c} = -M/Z \quad (29a)$$

$$= -C_m/C_Z \quad (29b)$$

$$y/s = L/Z \quad (30a)$$

$$= C_l/C_Z \quad (30b)$$

The force distribution for use in the above equations is found from Eqs. (7) and (9). To derive the stability derivatives, it is convenient to define a reference generalized deflection H , a reference temperature change T , and a reference load factor N . It is further convenient to consider an initial deflection mode $\{h_r\} = H_0\{h_r/H_0\}$ where H_0 is a reference initial deflection as distinct from that caused by the attitude change (additional deflection) specified by H . * These modifications permit Eq. (7) to be rewritten in a more general form

$$\begin{aligned}\{F_r\} = qS & \left(\{C_{zr}^{(e)}\} + (1/\bar{c})[W][C_{hs}] \left(H_0\{h_r/H_0\} \right. \right. \\ & \left. \left. + H\{h/H\} + T[a_T]\{t/T\} \right) \right) + N[M]\{n/N\} \quad (31)\end{aligned}$$

The initial coefficients and the stability derivatives are defined by

$$C_Z = C_{Z_0} + C_{ZH}H + C_{ZT}T + C_{ZN}N \quad (32)$$

$$C_m = C_{m_0} + C_{mH}H + C_{mT}T + C_{mN}N \quad (33)$$

$$C_l = C_{l_0} + C_{lH}H + C_{lT}T + C_{lN}N \quad (34)$$

where C_{ZH} , C_{ZT} , and C_{ZN} are examples of aerodynamic, thermal and inertial derivatives, respectively. The substitutions of Eqs. (9) and (31) into Eqs. (26b), (27b), and (28b) and a comparison with the coefficients of H , T , and N in Eqs. (32) through (34) yields the following. The initial

* See footnote, p. 3.

coefficients are

$$C_{Z_o} = [I][B] \{C_{z_r}\} \quad (35)$$

$$C_{m_o} = -(1/\bar{c})[x - x_o][B] \{C_{z_r}\} \quad (36)$$

$$C_{l_o} = (1/s)[y][B]\{C_{z_r}\} \quad (37)$$

where

$$\{C_{z_r}\} = \{C_{z_r}^{(e)}\} + (H_o/\bar{c})[W][C_{h_s}]\{h_r/H_o\} \quad (38)$$

The aerodynamic stability derivatives are

$$C_{Z_H} = [I][B] \{C_{z_{Hr}}\} \quad (39)$$

$$C_{m_H} = -(1/\bar{c})[x - x_o][B] \{C_{z_{Hr}}\} \quad (40)$$

$$C_{l_H} = (1/s)[y][B]\{C_{z_{Hr}}\} \quad (41)$$

where

$$\{C_{z_{Hr}}\} = (1/\bar{c})[W][C_{h_s}]\{h/H\} \quad (42)$$

The thermal derivatives are

$$C_{Z_T} = [I][B] \{C_{z_T}\} \quad (43)$$

$$C_{m_T} = -(1/\bar{c})[x - x_o][B]\{C_{z_T}\} \quad (44)$$

$$C_l_T = (1/s)[y][B]\{C_{z_T}\} \quad (45)$$

where

$$\{C_{z_T}\} = (1/\bar{c})[W][C_{hs}][a_T]\{t/T\} \quad (46)$$

Finally, the inertial derivatives are

$$C_{Z_N} = [I]\{C_{z_N}\} \quad (47)$$

$$C_{m_N} = -(1/\bar{c})[x - x_o]\{C_{z_N}\} \quad (48)$$

$$C_l_N = (1/s)[y]\{C_{z_N}\} \quad (49)$$

where

$$\{C_{z_N}\} = (K/\bar{c})[W][C_{hs}][A][a][M]\{n/N\} \quad (50)$$

The center of pressure for each of these loadings is found from Eqs. (29b) and (30b) using the appropriate coefficients or derivatives.

The rigid aerodynamic stability derivatives may be estimated from Eqs. (39) through (42) by taking $[B] = [I]$ (i.e., $q = 0$). Equations (39) through (42) may also be used to estimate dynamic stability derivatives by using the (complex) oscillatory AICs which are defined by

$$\{F\} = \rho \omega^2 b_r^2 s [W][C_h]\{h\} \quad (51)$$

By comparing this definition to the steady definition of Eq. (1), we see it is only necessary to replace $[C_{hs}]$ by $2k_r^2(\bar{c}s/S)[C_h]$ and to permit $\{h/H\}$ to become complex in order to make all of the preceding development applicable to the oscillatory case. Since this is a significant feature of the present analysis, we digress to illustrate the calculation in some detail. We choose as an example the estimation of the symmetrical longitudinal stability derivatives. We begin with the general expressions for the lift and moment coefficients for transient longitudinal motion.

$$C_Z = C_{Z_a} a + C_{Z_{Da}} (\dot{a}\bar{c}/2V) + C_{Z_q} (\dot{\theta}\bar{c}/2V) \\ + C_{Z_{D^2a}} (\ddot{a}\bar{c}^2/4V^2) + C_{Z_{Dq}} (\ddot{\theta}\bar{c}^2/4V^2) + \dots \quad (52)$$

$$C_m = C_{m_a} a + C_{m_{Da}} (\dot{a}\bar{c}/2V) + C_{m_q} (\dot{\theta}\bar{c}/2V) \\ + C_{m_{D^2a}} (\ddot{a}\bar{c}^2/4V^2) + C_{m_{Dq}} (\ddot{\theta}\bar{c}^2/4V^2) + \dots \quad (53)$$

If we truncate the series at the points shown in Eqs. (52) and (53), and consider the case of harmonic pitching ($\theta = a$) with amplitude a_0 , then

$$C_Z = a_0 \left[C_{Z_a} + ik \left(C_{Z_{Da}} + C_{Z_q} \right) - k^2 \left(C_{Z_{D^2a}} + C_{Z_{Dq}} \right) \right] \quad (54)$$

$$C_m = a_0 \left[C_{m_a} + ik \left(C_{m_{Da}} + C_{m_q} \right) - k^2 \left(C_{m_{D^2a}} + C_{m_{Dq}} \right) \right] \quad (55)$$

where the reduced frequency $k = \omega/\bar{c}/2V$. In the case of harmonic plunging ($\theta = 0$, $a = h/V$) with amplitude h_o , then

$$C_Z = h_o(2/\bar{c}) \left[ikC_{Z_a} - k^2 C_{Z_{Da}} - ik^3 C_{Z_{D2a}} \right] \quad (56)$$

$$C_m = h_o(2/\bar{c}) \left[ikC_{m_a} - k^2 C_{m_{Da}} - ik^3 C_{m_{D2a}} \right] \quad (57)$$

The lift and moment coefficients can also be found from Eqs. (39), (40), and (42) by making the substitutions noted above (i. e., $[B] = [I]$, and replacing $[C_{hs}]$ by $2k_r^2(\bar{c}s/S)[C_h]$).

$$C_Z = H[I] \{C_{z_{Hr}}\} \quad (58)$$

$$C_m = -H(1/\bar{c})[x - x_o] \{C_{z_{Hr}}\} \quad (59)$$

where

$$\{C_{z_{Hr}}\} = 2k_r^2(s/S)[W][C_h]\{h/H\} \quad (60)$$

To appraise the various longitudinal derivatives it is necessary to evaluate Eqs. (58) through (60) for both motions, pitching and plunging. For pitching about station x_1 , the reference deflection is taken as $H = a_o$, and the additional deflection mode is $\{h/H\} = \{x_1 - x\}$; for plunging, the reference deflection is $H = h_o$, and the additional deflection mode is $\{h/H\} = \{I\}$. The computational sequence is now evident. The evaluation of Eqs. (58) and (59) for the plunging motion yields two complex numbers which, when identified with the real and imaginary parts of Eqs. (56) and (57), lead to the four derivatives $C_{Z_{Da}}$, $C_{m_{Da}}$, $C_{Z_{D2a}}$, and $C_{m_{D2a}}$ (assuming, of course, that the static stability derivatives C_{Z_a} and C_{m_a} have already been determined).

A similar evaluation of Eqs. (58) and (59) for the pitching motion yields another set of two complex numbers which, when identified with the real and imaginary parts of Eqs. (54) and (55), and with appropriate utilization of the angle of attack derivatives determined previously, lead to the remaining derivatives C_{Zq} , C_{mq} , C_{ZDq} , and C_{mDq} . In a similar manner, many of the lateral-directional dynamic stability derivatives can be found from oscillatory AICs.

Our treatment of the stability derivatives provides a means of estimating a dimensionless spanwise load distribution and the spanwise variation of the chordwise center of pressure on a lifting surface. This calculation requires the data on which the AICs are based, i. e., the location and number of the chordwise control points, and the widths of the strips into which the surface has been divided. The load distribution coefficients are needed to make these calculations. The flexible load distribution coefficients are given by

$$\{C_{zf}\} = [B]\{C_z\} \quad , \quad (61)$$

where $\{C_z\}$ denotes any of the various distributions for the different loads except for the inertial loads; i. e., $\{C_z\}$ can be taken to represent any of $\{C_{zr}\}$, $\{C_{zHr}\}$, or $\{C_{zT}\}$; in the inertial case, $\{C_{zN}\}$ is used directly, i. e., $\{C_{zf}\} = \{C_{zN}\}$. The elements of $\{C_{zf}\}$ are listed in order for each surface strip as derived in the AICs and can be used to find the local dimensionless loading and center of pressure. Let us denote the sum of the load coefficients on the ith strip by

$$\Delta C_{Z_i} = \sum_{\text{strip } i} C_{zf} \quad (62)$$

and the moment about the leading edge by

$$\Delta C_{m_i} = \sum_{\text{strip } i} \xi C_{zf} \quad , \quad (63)$$

where ξ is the dimensionless chordwise location of each control point aft of the leading edge. Then the spanwise loading on the i th strip is given by

$$(c_f c / \bar{c})_i = -\Delta C_{Z_i} (s / \Delta y_i) \quad (64)$$

where Δy_i is the load strip width. The local center of pressure is given by

$$\xi_i = \Delta C_{m_i} / \Delta C_{Z_i} \quad (65)$$

The problem of reducing wind tunnel data is our last consideration. The purpose of a wind tunnel test is the measurement of the so-called rigid loads on the configuration (unless the model is specifically designed for aeroelastic measurements). But since no model is completely rigid, some aeroelastic correction can be made to any wind tunnel measurement. We now consider this correction. The situation is described by Eq. (61), which may be written as

$$\{C_{Z_f}^{(e)}\} = [B_m] \{C_{Z_r}^{(e)}\} \quad (66)$$

where $\{C_{Z_f}^{(e)}\}$ is the set of force coefficients measured on the flexible model, $[B_m]$ is the aeroelastic amplification matrix based on the model properties from Eq. (10), and $\{C_{Z_r}^{(e)}\}$ is the set of desired force coefficients on the rigid configuration. Obviously the rigid force coefficients follow from the inverse of Eq. (66)

$$\{C_{Z_r}^{(e)}\} = [B_m]^{-1} \{C_{Z_f}^{(e)}\} \quad (67)$$

The rigid force coefficients so determined then provide the starting point for the aeroelastic analysis of the prototype.

SECTION II

GENERAL DESCRIPTION OF INPUT

A. Units

All units are taken in the pound-inch system with two exceptions: the surface area is in square feet, and the dynamic pressure is in pounds per square foot.

B. Example Problem

We consider the static aeroelastic analysis of the five strip wing whose geometry is shown in Fig. 1. This is the jet transport wing analyzed by Bisplinghoff, Ashley, and Halfman throughout Ref. 7. We will use the following program options: trimmed loads with the structural loads suboption, divergence, aerodynamic stability derivatives (due to angle of attack), and inertial derivatives (due to symmetrical load factor). We proceed to assemble the data required as input to the program when it is to perform these options. The flexibility, mass, and aerodynamic influence coefficient matrices (all size 10×10) are printed in the program output example (pp. 45 through 48) and need not be shown here. The flexibility and mass matrices are taken from Ref. 1; the aerodynamic influence coefficients are developed from the subsonic lifting surface method of Ref. 8 at a Mach number of zero. We shall list only the additional data needed for the representative options. A basic list of constants can be used for all of the options and is given below:

$$c = 225 \text{ inches}$$

$$K = 1.0 \times 10^{-7}$$

$$S = 564.236 \text{ square feet}$$

$$Z = -41,919 \text{ pounds (this is the lift on one wing required in level flight neglecting any tail load or fuselage lift, and taking one-half the fuselage weight as 17,400 pounds)}$$

$$H = 1.0$$

$T = 0$
 $N = 1.0$
 $s = 500 \text{ inches}$
 $x_o = 0$
 $H_o = 0$

For the loads option we make the following assumptions: the aircraft is to be trimmed at three values of dynamic pressure: $q = 400, 800, \text{ and } 1200 \text{ psf}$; the aerodynamic matrix needs no experimental correction (the weighting matrix is taken as unity); no lift has been derived experimentally ($\{C_{z_r}^{(e)}\} = \{0\}$, size 10×1); there is no initial deflection mode ($\{h_r/H_o\} = \{0\}$, size 10×1); the additional deflection mode corresponds to zero angle of attack ($\{h/H\} = \{0\}$, size 10×1); and the symmetrical load factor distribution matrix is a unit column ($\{n/N\} = \{1\}$, size 10×1). The control point chordwise coordinate matrix for use in the trim analysis is

$$\{x\} = \begin{Bmatrix} 20.25 \\ -81.00 \\ 17.85 \\ -71.40 \\ 15.80 \\ -63.20 \\ 13.30 \\ -53.20 \\ 11.05 \\ -44.20 \end{Bmatrix} \text{ (inches)}$$

measured from the (unswept) 35 percent chord line as shown in Fig. 1. The final data necessary to compute the structural loads are the shear, moment, and torque coefficient matrices. Considering only the loads at the side of the fuselage, we have

$$[V/F] = [I], \text{ size } 1 \times 10,$$

$$[M/F] = [45 45 141 141 223 223 323 323 413 413],$$

$$[T/F] = [-20.25 +81.00 -17.85 +71.40 -15.80 +63.20 -13.30 +53.20 -11.05 +44.20].$$

The divergence option may be run simultaneously with the loads option since it requires only a portion of the above information. We request two divergence modes and dynamic pressures to be found.

The aerodynamic derivatives options will be carried out for the rigid case ($q = 0$) in addition to the previous list of dynamic pressures. The additional deflection mode $\{h/H\}$ used in the aerodynamic stability derivatives will be based on a one-radian angle of attack mode and is found from

$$\{h/H\} = -\{x/57.296\} = \begin{pmatrix} -0.35343 \\ 1.41371 \\ -0.31154 \\ 1.24616 \\ -0.27576 \\ 1.10304 \\ -0.23213 \\ 0.92851 \\ -0.19286 \\ 0.77143 \end{pmatrix} \text{ (per degree)}$$

The calculation of the load distribution and the rolling moment coefficient requires the following additional data shown in Fig. 1: the spanwise coordinate matrix

$$[y] = [90 90 186 186 268 268 368 368 458 458] \text{ (inches),}$$

and the width of each strip and the dimensionless chordwise location of each control point on the strip.

<u>Strip No.</u>	<u>Δy</u>	<u>ξ_f</u>	<u>ξ_a</u>
1	93	0.25	0.75
2	89	0.25	0.75
3	91	0.25	0.75
4	95	0.25	0.75
5	87	0.25	0.75

It is possible to perform all or any selected number of program options with one input deck if all data are real, although, in the example problem taking $\{h/H\} = \{0\}$ in the loads option does not permit calculation of the aerodynamic stability derivatives and taking $q = 0$ in the stability derivative option (to find derivatives for a rigid system) is not compatible with the trimmed loads option which requires $q > 0$. To avoid computing irrelevant results, we use two data decks, reproducing the cards (data) in the first deck that can be used as a part of the second deck.

C. Program Restrictions and Options

1. Maximum matrix size is 50×50 .
2. Maximum number of dynamic pressures per deck is 10.
3. Provision has been made to reserve a partition in the upper left-hand corner of the total AIC matrix for control points (and the flexibility and mass matrices must be compatible with this order of control points) whose aerodynamic forces may be neglected or found from an alternate theory to that used for the primary control points. This partition is termed the "external store" region since external stores are an example of a source of additional control points requiring such special consideration. The maximum number of control points that can be reserved for external stores is 49.
4. Maximum number of modes to be evaluated for the divergence option is 25.
5. For real and complex derivative calculations, the maximum number of strips is 20; the maximum number of control points per strip is 10.
6. Multiple options may be performed with one deck except for the following restrictions:
 - a. The structural loads option must be used as a suboption to the other loads options.

b. In any one input deck, all data must be for steady case (real) options or all data must be for oscillatory case (complex) options.

c. The divergence option cannot be used in the complex case.

7. Only one matrix of associated aerodynamic influence coefficients may be included in any one deck. When external stores are present, the matrix includes the AICs for the stores; however, this area may be set to zero.

8. In the oscillatory case, the following data must be input in complex form: AIC matrix, temperature mode, experimental forces, initial deflection mode, additional deflection modes, and load factor mode.

9. Program options and significant equation numbers as assigned in Part C, Section I are listed below.

- a. Loads for constant root angle of attack; Eqs. (31) and (9).
- b. Loads for trimmed condition; Eqs. (31) and (20).
- c. Loads for constant lift coefficient; Eqs. (22), (31), and (20).
- d. Divergence, Eq. (23).
- e. Initial coefficients; Eqs. (35) through (37).
- f. Aerodynamic stability derivatives; Eqs. (39) through (41).
- g. Thermal derivatives; Eqs. (43) through (45).
- h. Inertial derivatives; Eqs. (47) through (49).
- i. Experimental data reduction; Eq. (67).
- j. Structural loads; Eqs. (11) through (13).

SECTION III

DATA DECK SETUP

A. Loading Order

Data decks are loaded behind column binary deck LD003A. There are nineteen items that can be used in the data deck. The deck is set up with the items entered in the following order:

1. Heading card
2. Data deck control card
3. Constants cards
4. Dynamic pressure card(s)
5. Flexibility matrix
6. Aerodynamic matrix
7. Weighting matrix
8. Thermal matrix
9. Temperature mode
10. Experimental force column
11. Initial deflection mode
12. Additional deflection mode
13. Mass matrix
14. Load factor column
15. Chordwise coordinates
16. Spanwise coordinates
17. Strip widths and control point locations (percent chord)

18. Load coefficient matrices (shear, moment, torque)

19. Second and successive "additional deflection mode" columns

Items 1, 2, 3, and 6 must be present in all data decks; the presence (or absence) of the other items is determined by the option and data indicators used in the data deck control card (Item 2).

B. Input Data Description

1. The heading card may contain any alphanumeric characters desired in Columns 2 through 80. It is normally used for job title, engineer's name, and data.

2. Data deck control card (FORMAT 18I4): This card specifies which options are to be performed and also indicates the presence of certain data. The eighteen fields of this card are used as follows:

Field 1. Column 4 contains a 1 if load option 1 (LOADS FOR CONSTANT ROOT ANGLE OF ATTACK) is to be performed; it contains a zero or blank if not to be performed.

Field 2. Column 8 contains a 1 if load option 2 (LOADS FOR TRIMMED CONDITION) is to be performed, a zero or blank if not.

Field 3. Column 12 contains a 1 if load option 3 (LOADS FOR CONSTANT LIFT COEFFICIENT) is to be performed, a zero or blank if not.

Field 4. Column 16 contains the number of modes (25 maximum) of the DIVERGENCE option to be performed, a zero or blank if not.

Field 5. Column 20 contains a 1 if the INITIAL COEFFICIENTS option is to be performed, a zero or blank if not.

- Field 6. Columns 23 and 24 contain the number of solutions for AERODYNAMIC STABILITY DERIVATIVES desired. This option permits varying the "additional deflection mode" $\{h/H\}$ when the other data are unchanged. The first mode is included as Data Item 12, and the second and successive modes are included as Data Item(s) 19.
- Field 7. Column 28 contains a 1 if the problem is complex, a zero or blank if all data are real.
- Field 8. Column 32 contains a 1 if the THERMAL STABILITY DERIVATIVES option is to be performed, a zero or blank if not.
- Field 9. Column 36 contains a 1 if the INERTIAL DERIVATIVES option is to be performed, a zero or blank if not.
- Field 10. Column 40 contains a 1 if a weighting matrix is included in the data deck, a zero or blank if excluded.
- Field 11. Column 44 contains a 1 if a thermal matrix and associated temperature mode are included in the data deck, a zero or blank if excluded.
- Field 12. Column 48 contains a 1 if an experimental force column matrix is included in the data deck, a zero or blank if excluded.
- Field 13. Columns 51 and 52 contain the number of elements (control points) reserved for external stores, a zero or blank if none is reserved.
- Field 14. Columns 55 and 56 contain the number of dynamic pressures (10 maximum) for which cycling options (repeated for each "q") are to be performed.

Field 15. Column 60 contains a 1 if the EXPERIMENTAL DATA REDUCTION option is to be performed, a zero or blank if not.

Field 16. Column 64 contains a 1 if the STRUCTURAL LOADS option is to be performed, a zero or blank if not.

Field 17. Columns 67 and 68 indicate the order of the system contained in the data deck (50 maximum).

Field 18. Column 72 contains a 1 if the flexibility matrix is present in the data deck, a zero or blank if absent.

In the subsequent description of input data we find it convenient to refer to above fields 1, 2, 3, 4, 5, 6, 8, 9, 15, and 16 as Options identified by the respective field numbers. The other fields contain control numbers and will be referred to as Item 2, Field (respective number).

3. Constants cards (FORMAT 6E12.8): The two constants cards contain the items listed in the following order:

- a. CBAR: mean aerodynamic chord
- b. FLEXK: flexibility matrix normalizing constant (or scaling factor); when the matrix has not been normalized FLEXK = 1.0
- c. CAPS: surface reference area
- d. CAPZ: vertical force
- e. CAPH: generalized reference deflection
- f. CAPT: reference temperature change
- g. CAPN: reference load factor
- h. SMALS: surface span measured from root to tip
- i. CAPXO: coordinate pitching moment reference axis
- j. CAPHO: reference deflection for initial deflection mode

4. Dynamic pressures (FORMAT 6E12.8): If six or fewer dynamic pressures are listed, one card is used; seven through 10 pressures require two cards. The q card(s) are not required when performing Option 4 (divergence) above, but unless Item 2, Field 14 is zero or blank, the q's must be input and must agree with the number in this field.

5. The flexibility matrix [a] is input if its presence has been indicated in the data deck control card (Item 2, Field 18). If not included as input, a rigid case is assumed ($[a] = [0]$). The following card order and formats must be used when the matrix is input.

a. Control card (FORMAT 18I4)

Field 1. Columns 3 and 4 contain m, the number of rows in the matrix (≤ 50).

Field 2. This field is not used; it may be left blank.

Field 3. Column 12 contains IFORM; if IFORM = 1, the matrix elements are to be input using FORTRAN FORMAT 6E12.8; if IFORM = 0, the elements will be input using column binary format.

Field 4. Column 16 contains IROW; if IROW = 1, the matrix elements are input by row; if IROW = 0, the elements are input by column.

b. Matrix elements (use format specified above)

If IFORM = 1, and IROW = 1: use FORMAT 6E12.8 and input the matrix element by row; each new row starts on a new card (line).

If IFORM = 1, and IROW = 0: use FORMAT 6E12.8 and input the elements by column with each new column beginning on a new card.

If IFORM = 0, IROW must = 0: the matrix elements are input using column binary format. This format should be used only if the data are available as punched-card output from appropriate computer programs. The elements must be punched by columns; Column 1 starts in Origin 1 and Column 2 starts in Location (1 + m). A TRA card must end the deck. (This transfer card has a 7 and a 9 punch in Column 1, Columns 2 through 72 are blank, and Columns 73 through 80 will contain the characters used for identifying and sequencing the deck.)

6. The aerodynamic matrix [C_h] is always present in the data deck. It consists of two parts if external stores have been reserved in Item 2, Field 13, and it is real (steady case) unless indicated as complex (oscillatory case) in Item 2, Field 7. The [C_h] matrix must be entered as follows with this exception: Items a and b (below) will be omitted when no external stores are reserved:

a. Control card for store [C_h] (FORMAT 18I4)

Field 1. Columns 3 and 4 contain m, number of control points reserved for external stores (≤ 49); m = 0 will direct the program to set the store [C_h] to zero.

Field 2. This field is not used, it may be left blank.

Field 3. Column 12 contain IFORM as defined in Item 5a.

Field 4. Column 16 contains IROW as defined in Item 5a.

b. Store matrix elements (format specified in Fields 3 and 4, above control card): Omit this input if m = 0 is used in the control card. When the external stores [C_h] matrix is input, use the format in the manner described in Item 5b. If the matrix elements are complex numbers (oscillatory case) consider the matrix size as $m \times 2m$ (imaginary parts of the elements form the even-numbered columns) and input as though all elements were real numbers.

c. $1/k_r$ card (FORMAT 6E12.8): The reference reduced velocity card is always present. For the steady case, it may be blank or contain any number, but for the oscillatory case it must be the $1/k_r$ associated with the aerodynamic matrix.

d. Control card for surface [C_h] matrix (FORMAT 18I4)

Field 1. Columns 3 and 4 contain m, the number of control points on the surface. (m = size of system minus number of store control point.)

Field 2. Columns 7 and 8 contain L, the number of strips (partitions) in the surface. L = 1 for a full (unpartitioned) matrix.

Field 3. Column 12 contains IFORM as previously defined.

Field 4. Column 16 contains IROW as previously defined.

e. The input listed below must be repeated for each partition (i = 1, L).

(1) Partition size (FORMAT 18I4)

Field 1. Columns 3 and 4 contain n, the number of control points on strip i (size of partition i). If L = 1, n = total number of control points on the surface.

(2) Matrix elements in partition i (format specified in control card, Item 6d).

When the matrix is for the steady case the elements in each partition are input in the same manner as the elements in the [a] matrix (Item 5b). In the oscillatory case, the elements are entered in the same manner as described for the stores oscillatory $[C_h]$ matrix (Item 6b).

Note: Punched cards output from IBM programs based on the sources listed below may be used (with no alterations) for Items 6c, 6d, and 6e when the theory is appropriate to the problem. Punched cards output from the program based on slender-body theory may be used for Items 6a and 6b if the first card ($1/k_r$) is removed from the deck. The list shown is complete only at this writing; additional compatible sources are currently under development.

7. Weighting matrix: The weighting matrix $[W]$ is input if its presence has been indicated in Item 2, Field 10. The matrix is entered with formats identical to those given for the $[C_h]$ matrix (Item 6a, b, c, d, e) with three exceptions: (1) the $1/k_r$ card (Item 6c) is omitted; (2) in repeating Item 6a if $m = 0$ the program will use a unit matrix for the store $[W]$; and (3) the matrix is always real. It is not required that $[C_h]$ and $[W]$ be input with the same format in the same data deck; i.e., one may be in column binary while the other uses FORTRAN format, and one may be partitioned while the other is a full matrix.

8. Thermal influence coefficients matrix: The thermal matrix $[a_T]$ is input when Item 2, Field 11 notes its presence. The matrix is required input for Option 8. The formats for entering $[a_T]$ are the same as those used for the flexibility matrix: Items 5a and 5b.

9. Temperature distribution column (FORMAT 6E12.8): The temperature mode $\{t/T\}$ always accompanies the above thermal matrix. For steady cases (real AICs), the $\{t/T\}$ matrix is entered as one column, six elements per card. For oscillatory cases (complex AICs), the mode is complex with the imaginary part considered as a second column; tabulate by column with the second column starting a new card.

10. Experimental force column (FORMAT 6E12.8): The experimental force column $\{C_{zr}^{(e)}\}$ is input only if its presence has been indicated by Item 2, Field 12. The column (real or complex) is entered in the same manner as the column in Item 9.

11. Initial deflection mode (FORMAT 6E12.8): The initial deflection mode $\{h_r/H_0\}$, must be present to perform Option(s) 1, 2, 3, and/or 5. Again refer to Item 9 for entering the column (real or complex). If all elements in the column are zero, a sufficient number of blank cards may be used.

12. Additional deflection mode (FORMAT 6E12.8): The additional deflection $\{h/H\}$ must be included for Option(s) 1, 2, 3, and/or 6. See Items 9 and 11 for inputting this column (real or complex).

13. Mass matrix: The mass matrix $[M]$ must be in the data deck when performing Option(s) 1, 2, 3, and/or 9. The matrix is input as follows:

a. Control card 1 (FORMAT 18I4): Field 1 must contain NRC, order of the matrix (same as Item 2, Field 17).

b. Control card(s) 2 through 7 (FORMAT 18I4): Field 1 and consecutive fields in control card 2 and successive control cards contain in order LL_1 , LH_1 , LL_2 , LH_2 , ..., LL_{NRC} , LH_{NRC} . LL_i is the row number where the first nonzero element appears in column i; LH_i is the row number where the last nonzero element appears in column i. If only one nonzero element is in column i, its row number must be used for both LL_i and LH_i .

c. Elements in $[M]$ matrix (FORMAT 6E12.8): The elements are entered by column as shown below. Each column starts on a new line (card).

Column 1: elements LL_1 through LH_1

Column 2: elements LL_2 through LH_2

Column NRC: elements LL_{NRC} through LH_{NRC}

Any zero elements between LL_i and LH_i must be entered or their respective fields left blank. If all elements in a column are zero, then at least one element must be entered as zero (a blank card may be used); LL_i and LH_i for this zero element must appear in the above control cards.

14. Load factor column (FORMAT 6E12.8): The load factor column $\{n/N\}$ is included if [M] is used (Option(s) 1, 2, 3, and/or 9). If no correction is desired, input a unit column. The column is real for steady cases and complex for oscillatory cases. (See Item 9 for column input.)

15. Chordwise coordinates (FORMAT 6E12.8): The control point coordinate matrix $\{x\}$ or $[x]$ is input for Option(s) 2, 3, 5, 6, 8, 9, and/or 15. The matrix is entered only once (six elements per card) for any combination of the above options.

16. Spanwise coordinates (FORMAT 6E12.8): A spanwise control point coordinate matrix $[y]$ must be used with Option(s) 5, 6, 8, 9, and/or 15. The elements in $[y]$ are the control point distances from the roll axis.

17. Strip widths and control point locations (percent chord): The strip widths Δy_i and the control point locations $\xi_{i,j}$ (given as a fraction of the local chords) are required for Option(s) 5, 6, 8, 9, and/or 15. These data have the following input format.

a. Control card(s) (FORMAT 18I4)

Field 1. This field must contain $NSTRP$ = number of surface strips (maximum of 20 for above options). Do not include external stores as strips.

Field 2. Field 2 and successive fields contain $NCPT_i$ = number of control points (≤ 10) on strip i . ($i = 1, NSTRP$)

b. Δy_i and $\xi_{i,j}$ ($j = 1, NCPT_i$) (FORMAT 6E12.8): These data are entered by strips; each strip requires one line (card) when $NCPT \leq 5$ and two cards when $NCPT > 5$. Start with the first card for strip 1 and input the data as follows:

Field 1. Δy_1 : width of strip 1.

Field 2. ξ_1 1: location of first control point for strip 1.

Field 3. ξ_1 2: location of second control point for strip 1.

.

.

.

Field $(NCPT_1 + 1)$. $\xi_1 NCPT_1$: location of last control point for strip 1. (If $NCPT > 5$, then ξ_1 6 would be in Field 1, second card).

Repeat the above for each strip

18. Transformation matrices for structural loads: The shear, moment, and torque matrices, [V/F], [M/F], and [T/F], are input only if Option 16 is selected in conjunction with Option(s) 1, 2, or 3. The elements in any specific row of each matrix are the loads at a particular station due to a unit control point force.

The matrices are input in the order in which they are listed (above pp.) with each using the same format (similar to the mass matrix but input by rows instead of columns). The format for [V/F] is given below; the same format is used for [M/F] and [T/F].

a. Control card 1 (FORMAT 18I4): Field 1 contains NVMT, the number of rows in [V/F]. Note the matrix size is $(NVMT \times NRC)$, where NRC agrees with Item 2, Field 17 and $NVMT \leq 20$.

b. Control card(s) 2 through 7 (FORMAT 18I4): Field 1 and consecutive fields of these cards contain $LOW_1, LHIGH_1, LOW_2, LHIGH_2, \dots, LOW_{NVMT}, LHIGH_{NVMT}$. LOW_i is the column number of the first nonzero element in row i , and $LHIGH_i$ is the column number of the last nonzero element in row i . ($i = 1, NVMT$)

c. Elements of [V/F] (FORMAT 6E12.8): The elements are entered by row in the same manner as the columns in [M]. (Item 13c).

19. Second and successive "additional deflection mode" columns
(FORMAT 6E12.8): It is possible to vary the additional deflection modal column
 $\{h/H\}$ to obtain two or more solutions for real or complex aerodynamic
stability derivatives. Use the input format given for Item 9 (or 12) repeating
the format for each new column.

C. Table of Option Requirements

To aid the program user in data deck setup, the following table shows
which of the above described 19 data items are required to make up a data
deck for any option.

DATA ITEM

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19
OPTION	P	P	P	P	P	P	O	O	O	O	P	P	P	P	A	A	A	-	A
1	P	P	P	P	P	P	O	O	O	O	P	P	P	P	P	A	A	-	A
2	P	P	P	P	P	P	O	O	O	O	P	P	P	P	P	A	A	-	A
3	P	P	P	P	P	P	O	O	O	O	P	P	P	P	P	A	A	-	A
4	P	P	P	A	P	P	O	A	A	A	A	A	A	A	A	A	A	A	A
5	P	P	P	P	O	P	O	A	A	O	P	A	A	A	P	P	P	A	A
6	P	P	P	P	O	P	O	A	A	A	A	P	A	A	P	P	P	A	O
8	P	P	P	P	O	P	O	P	P	A	A	A	A	A	P	P	P	A	A
9	P	P	P	P	O	P	O	A	A	A	A	A	A	P	P	P	P	A	A
15	P	P	P	P	P	P	O	A	A	P	A	A	A	A	P	P	P	A	A
16	← Set up for option (1, 2, or 3) being performed →																		A P A

P = must be present; A = must be absent; O = optional inclusion;

-- present when Option 16 is used with Option 1, 2, or 3.

Note: The above table applies to options performed singly with the exception of Option 16 which must be used concurrently with Option 1, 2, or 3. Where multiple options are to be performed with one data deck and an item must be present for one of the options and absent for another, that item must be included in the data deck. Also any data item indicated as present in the control card (Item 2) must be included in the deck, even though it may not be used in the particular option(s) chosen.

D. Example Keypunch Forms

Example keypunch forms are given on the following pages. Columns 73 through 80 are reserved for data deck identification and sequencing. Only the cards with sequencing are used in the two data decks set up for the example problem; the lines with Columns 73 through 80 left blank are for description of input.

EXAMPLE PROBLEM - TRIMMED LOADS AND DIVERGENCE OPTIONS										MM030001									
Heading Card																			
Data Deck Control Card										3 1 1 1 0 1 0 2									
Constant Cards										1 -1 0 0 0 0 0 0 0 0									
Dynamic Pressures										+0.0 +0.0 +0.0 +0.0 +0.0 +0.0 +0.0 +0.0 +0.0 +0.0									
Control Card for Flexibility Matrix [a]										+4.00 +0.3+8.00 +0.3+1.200 +0.4 0.5 0.5									
[a] Matrix Elements										1.0 1 1 1 0 0 0 0 0 0									
1/k_r Card										+0 +0.0 +0.0 +0.0 +0.0 +0.0 +0.0 +0.0 +0.0 +0.0									

The matrix elements can be seen in the printed output. The control card gives the size and specifies the format (FORTRAN 6(12.8, by rows) used to input [a] in this problem. (See Section III, Part B, Item 5 for other input formats.)

The data deck for the example derivative option is set up using the above sequenced cards plus the following cards from the previous deck.

MW030003-04	-	Constants Cards
06-26	-	Flexibility Matrix
27-49	-	Aerodynamic Matrix
50-65	-	Weighting Matrix
70-84	-	Mass Matrix and Load Factor Column
MW030085-86	-	Circumferential Coordinates

SECTION IV
PROGRAM OUTPUT

A. Output for Each Option

In addition to all input data, the following is printed for each option.

1. Option 1 (for each dynamic pressure)
 - a. Deformation mode
 - b. Total deflection mode
 - c. Final aerodynamic force distribution
 - d. Total force distribution
2. Option 2 (for each dynamic pressure)
 - a. Incremental pitch angle
 - b. Deformation mode
 - c. Total deflection mode
 - d. Final aerodynamic force distribution
 - e. Total force distribution
3. Option 3 (for each dynamic pressure)
 - a. Aerodynamic lift
 - b. Incremental pitch angle
 - c. Deformation mode
 - d. Total deflection mode
 - e. Final aerodynamic force distribution
 - f. Total force distribution

4. Option 4 (divergence)

a. For each mode: mode number, eigenvalue, divergence pressure, and number of iterations

b. Divergence modes (eigenvectors)

c. Check eigenvalues

d. Check eigenvectors

5. Options 5, 6, 7, 8, and 9 (for each dynamic pressure)

a. Distributed force coefficients

b. Aerodynamic normal force, pitching moment, and rolling moment coefficients

c. Total chordwise center of pressure

d. Total spanwise center of pressure

e. For each strip: spanwise loading and local center of pressure.

6. Option 15 (for each dynamic pressure)

a. Corrected experimental force coefficients

b. Aerodynamic normal force, pitching moment, and rolling moment coefficients

c. Total chordwise center of pressure

d. Total spanwise center of pressure

e. For each strip: spanwise loading and local center of pressure.

7. Option 16 (for each dynamic pressure)

a. All data listed under the associated option (1, 2, or 3).

b. Shear, moment, and torque at load stations.

B. Example Printout

The printout for the example problem is shown on the following pages. Some of the results shown may be compared with similar calculations presented in Ref. 7.

SECTION V

PROCESSING INFORMATION

A. Operation

FORTRAN II MONITOR system

B. Estimated Machine Time

Because of the number of variables involved such as options, order of system, number of dynamic pressures, etc., it is not possible to give a practical method of estimating machine time. When the data are appropriate, considerable time may be saved by performing as many options as possible in one machine pass. Also, complete but independent data decks may be stacked to save program read-in time.

C. Machine Components Used

About 26,000 core storages

Standard FORTRAN input tape (NTAPE2)

Standard FORTRAN output print tape (NTAPE3)

Four utility tapes (NTAPE4, NTAPE5, NTAPE6, NTAPE8)

SECTION VI

PROGRAM NOTES

A. Subroutines Used

In addition to the main program (page 77) the following subprograms were used.

1. MPRINT, prints matrix in matrix format (page 91).
2. MMULTD, computes the product $[C]$ of the two matrices $[A]$ and $[B]$ (page 95).
3. MREAD, reads a matrix in either column binary or FORTRAN format (page 98).
4. BINRD, reads column binary cards (page 103).
5. RDLN, reads and prints title card (page 113).
6. MNVRSX, computes the inverse of a complex matrix (page 115).
7. INVERS, computes the inverse of a real matrix (page 118).
8. SWEEPX, computes true mode and sweeps it from the related matrix (page 123).
9. CENTER, computes the aerodynamic coefficients, centers of pressure, and spanwise loadings (page 128).
10. LOADS, computes the three loads options and the structural loads suboption (page 133).
11. DERIV, computes the flexible load coefficients used in the derivative options (page 143).
12. MITER, matrix iteration (page 149).
13. NPNRMX, vector normalization (page 160).
14. DIVERG, divergent pressure calculations (page 165).

B. Generalized Tapes

Input, print, and utility tapes in this coding are defined as logical units 2, 3, 5, 6, 7, and 8; however, these may be altered by placing the desired units on symbolic cards HMO3O827 through HMO3O832 in the main program.

SYMBOLIC LISTING

Some of the program FORTRAN symbols are defined below.

<u>FORTRAN Symbols</u>	<u>Definitions</u>
A(I,J), B(I,J), C(I,J)	Elements of matrix "working" arrays; also elements of [a], [C _h], and [W]
ATTIT(I,J)	Element of column matrix representing the product [a _T]{t/T}
C1OKR	1/k _r
CAPH	H
CAPHO	H _o
CAPN	N
CAPS	S (reference area)
CAPT	T
CAPXO	x _o
CAPZ	Z
CBAR	c̄
CNIN(I,J)	Element of column matrix representing the product [M]{n/N}
CZRE(I,J)	Element of experimental force column matrix
DELY(J)	Δy _j (width of strip j)
F(I,J)	Element of total force distribution column
FA(I,J)	Element of final aerodynamic force distribution column
FLEXK	K
FMOM(J,K)	Element in load coefficient matrix [M/F]
FR(I,J)	Element of rigid force distribution column
HADD(I,J)	Element of additional deflection mode column
HR(I,J)	Element of initial deflection mode column

<u>FORTRAN Symbols</u>	<u>Definitions</u>
IFORM	IFORM = 1 if matrix is in FORTRAN format; = 0 if matrix is in column binary format
IROW	IROW = 1 if matrix is input by rows; = 0 if matrix is input by columns
L	Number of strips (partitions) in the surface aerodynamic matrix
LH(K)	Row number of last nonzero element in column k of mass matrix
LHIGH(J)	Column number of last nonzero element in row j of [V/F], [M/F], or [T/F]
LL(k)	Row number of first nonzero element in column k of mass matrix
LOW(J)	Column number of first nonzero element in row j of [V/F], [M/F], or [T/F]
NCPT(J)	Number of control points for strip j
NEXT	Number of external stores reserved
NOP(I)	Option i, Field i of control card (data Item 2)
NQ	Number of dynamic pressures read in
NRC	Order of current case
NSTRP	Number of surface strips used for derivatives options
NVMT	Number of rows in [V/F], [M/F], or [T/F]
Q(I)	(ith) dynamic pressure
SHEAR(J,K)	Element in load coefficient matrix [V/F]
SMALS	s
TCCP	Chordwise center of pressure
TORQU(J,K)	Element in load coefficient matrix [T/F]
TSCP	Spanwise center of pressure
X(I)	Element in chordwise coordinate matrix
Y(I)	Element in spanwise coordinate matrix
ZI(I,J)	Location of <u>j</u> th control point for strip i

The symbolic listing of the program is shown on the following pages.

***** POSITION FOR RETRY OR EXIT. *****

IF A BCD RECORD IS

ENCOUNTERED, THE C(IAR)

OF CHANNEL WILL

DENOTE ONLY 14 WORDS

TRANSMITTED. A BINARY

RECORD WILL BE DENOTED

BY A GREATER NUMBER OF

WORDS TRANSMITTED.

(THE SCHX INSTRUCTION IS ABSENT

FROM IOS. MUST BUILD ONE.)

Aerospace Corporation, El Segundo, California. QUASI-STATIC AERO-THERMO-ELASTIC ANALYSIS: ANALYTICAL DEVELOPMENT AND COMPUTATIONAL PROCEDURE, prepared by W. P. Rodden, E. F. Farkas, and H. A. Malcolm. 1 March 1963. [172] p. incl. illus. (Report TDR-169(3230-11)TN-8; SSD-TDR-63-14) (Contract AF 04(695)-169). Unclassified report	A collocation formulation is used as the basis for a unified approach to the various quasi-static aero-thermo-elastic problems. These problems include rigid and flexible load distribution, divergence, estimation of rigid and flexible static and dynamic stability derivatives, and the correction of wind tunnel data measured on flexible models. The formulation utilizes structural, thermal, and aero-dynamic influence coefficients. The Aerospace IBM 7090 Computer Program No. LD003A provides the solution to the above problems. The program (over)	UNCLASSIFIED	UNCLASSIFIED
Aerospace Corporation, El Segundo, California. QUASI-STATIC AERO-THERMO-ELASTIC ANALYSIS: ANALYTICAL DEVELOPMENT AND COMPUTATIONAL PROCEDURE, prepared by W. P. Rodden, E. F. Farkas, and H. A. Malcolm. 1 March 1963. [172] p. incl. illus. (Report TDR-169(3230-11)TN-8; SSD-TDR-63-14) (Contract AF 04(695)-169). Unclassified report	A collocation formulation is used as the basis for a unified approach to the various quasi-static aero-thermo-elastic problems. These problems include rigid and flexible load distribution, divergence, estimation of rigid and flexible static and dynamic stability derivatives, and the correction of wind tunnel data measured on flexible models. The formulation utilizes structural, thermal, and aero-dynamic influence coefficients. The Aerospace IBM 7090 Computer Program No. LD003A provides the solution to the above problems.
